Painlevé kernels in Hermitian matrix models

Maurice Duits*

Abstract

After reviewing the Hermitian one matrix model, we will give a brief introduction to the Hermitian two matrix model and present a summary of some recent results on the asymptotic behavior of the two matrix model with a quartic potential. In particular, we will discuss a limiting kernel in the quartic/quadratic case that is constructed out of a 4×4 Riemann-Hilbert problem related to Painlevé II equation. Also an open problem will be presented.

1 Introduction

The study of the local statistics in large random systems of interacting particles, such as the eigenvalues of large random matrices, is a central theme in random matrix theory. The universality principle states that the local statistics obey laws that have a universal character and do not depend on the precise definition of the underlying probability measure but rather on some general characteristics. Generic examples are the sine universality in the bulk and Airy universality near a soft edge. However, there may be singular points near which the limiting local correlations are described by more complicated universality classes. In some of these cases remarkable connections to Painlevé equations have been found.

A model on which substantial progress has been made is the Hermitian one matrix model (also called the Unitary Ensembles). A milestone was the rigorous verification of the bulk and soft edge universality conjectures in [19, 20] based on the orthogonal polynomial approach and Riemann-Hilbert techniques. Among further important developments are the treatment of the three types of singular points that can occur. Near two of those the local correlations are described by Ψ-functions associated to special solutions to members of the Painlevé I and II hierarchies [7, 14, 15, 16, 55].

In this paper, our main focus will be on the Hermitian two matrix model which is a natural extension of the Hermitian one matrix model. There is strong evidence that the two matrix model gives rise to a family of singular situations that is much larger than the one for the one matrix model. For example, it is believed to be a good model for generating the (p, q) conformal minimal models

*Department of Mathematics, Royal Institute of Technology (KTH), Lindstedtsvägen 25, SE-10044 Stockholm, Sweden. Supported by the grant KAW 2010.0063 from the Knut and Alice Wallenberg Foundation.

[17]. The classification and characterization of the local correlations near the singular points is an important open problem in random matrix theory.

By using the Riemann-Hilbert approach for the associated biorthogonal polynomials, we recently analyzed the asymptotic behavior of the two matrix model with one quartic potential [22, 23, 25, 26, 49]. Here we will report on that progress. As it is important to compare our results with the results for the one matrix model, we provide in Section 2 a brief overview of the one matrix model and the singular cases that can appear. In particular, we review the results on the case of one to two interval transition related to the Painlevé II equation. This situation will also return in our discussion on the two matrix model.

In Section 3 we discuss the definition of the Hermitian two matrix model in its general form and the relation with certain biorthogonal polynomials. In Section 4 we first discuss the vector equilibrium problem that was a key ingredient for the asymptotic analysis [25, 26, 49] of the Riemann-Hilbert problem for the biorthogonal polynomials. Second, we present a phase diagram and a new critical phenomenon for the quartic/quadratic case that we analyzed in [22]. Interestingly, the limiting kernel is constructed out of a 4×4 Riemann-Hilbert problem associated to the Hastings-McLeod solution to the Painlevé II equation.

Finally, in Section 5 we show that the singular case of [22] can be embedded into a larger class of singular cases for which a rigorous analysis may be within reach. We leave this as an open problem.

2 One matrix model

The Hermitian one matrix model is defined as the probability measure on the space of $n \times n$ Hermitian matrices given by

$$\frac{1}{Z_n} \exp\left(-n \operatorname{Tr} V(M)\right) \mathrm{d}M, \tag{2.1}$$

where V is a polynomial of even degree and positive leading coefficient, $\mathrm{d}M = \prod_{i=1}^n \mathrm{d}M_{ii} \prod_{i<j} \mathrm{d}\operatorname{Re} M_{ij}\, \mathrm{d}\operatorname{Im} M_{ij}$, and Z_n is a normalizing constant. We will be concerned with the limiting behavior of the eigenvalues of a matrix M taken randomly from (2.1) as $n \to \infty$.

2.1 Global limit

By integrating over the unitary group the probability measure (2.1) reduces to the following probability measure on the eigenvalues

$$\frac{1}{\tilde{Z}_n} \prod_{i<j} (x_i - x_j)^2 \mathrm{e}^{-n \sum_{j=1}^n V(x_j)}\, \mathrm{d}x_1 \cdots \mathrm{d}x_n. \tag{2.2}$$

Because of the Vandermonde determinant the probability of for eigenvalues to cluster is small and hence the eigenvalues appear to repel each other. On the other hand, due to the exponential factor the probability of finding the

eigenvalues spread out is small and hence V acts a confining potential. As $n \to \infty$ the eigenvalues seek the equilibrium situation for these two competing mechanisms. More precisely, the empirical eigenvalue distribution $\frac{1}{n}\sum_{j=1}^n \delta_{x_j}$ converges weakly to μ_V almost surely, where μ_V is the unique minimizer of the energy functional

$$I_V(\nu) = \iint \log \frac{1}{|x-y|} \mathrm{d}\mu(x)\mathrm{d}\mu(y) + \int V(x)\mathrm{d}\mu(x), \tag{2.3}$$

minimized over all probability measure μ on $\mathbb{R}$.

This minimization problem can be solved in terms of an algebraic curve. There exists a polynomial Q of degree $\deg V - 2$ such that the function

$$\xi(x) = V'(x) - \int \frac{1}{x-s} \mathrm{d}\mu_V(s),$$

is a solution to the equation

$$\xi^2 - V'(x)\xi + Q(x) = 0. \tag{2.4}$$

This curve can be derived using the variational conditions corresponding to minimizing (2.3). It can also be derived by a change of variables in (2.1) (see for example [39]). It particularly implies that μ_V is absolutely continuous with a density

$$\rho(x) = \frac{\mathrm{d}\mu_V}{\mathrm{d}x}(x) = \frac{1}{\pi}\sqrt{R_-(x)}, \qquad x \in \mathbb{R}.$$

where R_- is the negative part of $R(x) = V'(x)^2/4 - Q(x)$ (so $R = R_+ - R_-$). In particular, one readily verifies that the support $S(\mu_V)$ of μ_V consists of a finite number of intervals. In the generic situation, the density is strictly positive in the interior and vanishes as a square root at the endpoints.

2.2 Airy and sine universality

Although the eigenvalue distribution on the global scale has a deterministic limit, interesting point processes are observed by scaling the eigenvalues around a point in the support of μ_V such that the average distance between eigenvalues is of finite order. Before we describe the asymptotic behavior on the local scale, we discuss the orthogonal polynomials that integrate the one matrix model.

For $k \in \mathbb{N}_0$ let $p_{k,n}$ be the unique monic orthogonal polynomial of degree k with respect to $\mathrm{e}^{-nV(x)}\mathrm{d}x$ on $\mathbb{R}$, i.e.

$$\int p_{k,n}(x) x^j \mathrm{e}^{-nV(x)} \mathrm{d}x = 0, \quad j = 0, \ldots, k-1.$$

Moreover, let K_n be the reproducing kernel

$$K_n(x,y) = \mathrm{e}^{-n(V(x)+V(y))/2} \sum_{k=0}^{n-1} \frac{1}{h_{k,n}^2} p_{k,n}(x) p_{k,n}(y),$$

where $h_{k,n}^2 = \|p_{k,n}\|^2_{\mathbb{L}_2(\mathrm{e}^{-nV(x)}\mathrm{d}x)}$. Then the eigenvalues of M taken randomly with respect to (2.1) form a determinantal point process with kernel K_n. This means that (2.2) and the marginal densities (or, up to a scalar, the correlation functions) can be written as

$$\underbrace{\int\cdots\int}_{n-k \text{ times}} \mathcal{P}(x_1,\ldots,x_n)\mathrm{d}x_{k+1}\cdots\mathrm{d}x_n = \frac{(n-k)!}{n!}\det\left(K_n(x_i,x_j)\right)_{i,j=1}^k, \tag{2.5}$$

for $k=1,\ldots,n$. For more details on determinantal point processes we refer to [10, 38, 40, 45, 47, 56]. The main point is that K_n characterizes the point process entirely and in order to find the asymptotic behavior of the process on the local scale it suffices to compute the scaling limits of the kernel K_n.

Let $x^* \in S(\mu_V)$ such that $\rho(x^*)>0$. Then for large n the distance between eigenvalues near x^* is of order $\sim n^{-1}$ and we have the limit

$$\lim_{n\to\infty} \frac{1}{n\rho(x^*)} K_n\left(x^*+\frac{x}{n\rho(x^*)}, x^*+\frac{y}{n\rho(x^*)}\right) = \frac{\sin\pi(x-y)}{\pi(x-y)}. \tag{2.6}$$

uniformly for x,y in compact subsets. Note that the right-hand side is independent of x^* and V. This is the celebrated principle of sine universality in random matrix theory. In [19, 20] it was proved by using RH methods for analytic potentials V and later extended in [48, 54] to more general situations. It should also be noted that in recent years there has been an interesting development on proving (2.6) by using more classical methods for orthogonal polynomials, obtaining even more general results. See [46] for a survey.

Now let x^* be an endpoint of an interval in the support of μ_V and assume that we are in the generic situation so that the density vanishes as a square root at x^*. Then the distance between eigenvalues near x^* is of order $\sim n^{-2/3}$ and we have the scaling limit

$$\lim_{n\to\infty} \frac{\pm 1}{(cn)^{2/3}} K_n\left(x^*\pm\frac{x}{(cn)^{2/3}}, x^*\pm\frac{y}{(cn)^{2/3}}\right) = \frac{\mathrm{Ai}(x)\,\mathrm{Ai}'(y)-\mathrm{Ai}'(x)\,\mathrm{Ai}(y)}{x-y} \tag{2.7}$$

with $+$ is if x^* is a right endpoint and $-$ if x^* is a left endpoint. Here Ai stands for the Airy function.

2.3 Singular points

The scaling limits (2.6) and (2.7) are valid for the regular points of the spectral curve (2.4). It may happen that there are singular points and around these points we obtain different and more complicated limits. There are three types of singular points that can occur.

1. **Exterior singular point** a point outside the support where we have equality in the variational inequality for the equilibrium problem (2.3);

2. **Interior singular point** a point x^* in the interior of S_{μ_V} such that $\rho(x) = c(x-x^*)^{2m}(1+o(1))$ as $x \to x^*$ for some $m \in \mathbb{N}$ and $c > 0$;
3. **Singular edge point** an endpoint x^* of one of the intervals in S_{μ_V} such that $\rho(x) = c(x \pm x^*)^{2m+1/2}(1+o(1))$ as $x \to x^*$ for some $m \in \mathbb{N}$ and $c > 0$ (here $\pm$ depends whether we have a right or left endpoint).

By varying the coefficients of V these singular points correspond to transitions in the support $S(\mu_V)$. For example, we can let an interval in the support shrink to a point after which it disappears, leading to an exterior singular point. By letting two intervals merge to one we create an interior singular point. If both transitions happen simultaneously near the same point we obtain a singular edge point. By involving several intervals simultaneously we obtain the higher order singularities.

Near singular points, the local correlations have limits that are different from (2.6) and (2.7). The singular edge points and interior singular point are related to special solutions to members of the Painlevé I and Painlevé II hierarchy respectively, which we will discuss in more detail. The treatment of exterior singular points of the first type can be found in [6, 13, 50] but they are not related to the Painlevé transcendents.

2.3.1 Interior singular points

We will now discuss the singular case of quadratic vanishing at an interior point in more detail. This situation will also play a role in the upcoming discussion on the two matrix model.

Let us consider the double well potential

$$V(x) = \tfrac{1}{4}x^4 - x^2.$$

In this case, the origin is a singular interior point and the density vanishes quadratically

$$\rho(x) = \tfrac{2}{\pi}x^2\sqrt{2-x^2}\mathrm{d}x$$

This situation was analyzed in [7]. For the treatment of more general potentials leading to quadratic vanishing at an interior point see [15, 55].

The singular case is analyzed by means of a double scaling limit. We introduce a parameter λ and consider the random matrix model with $V_\lambda = \lambda V$. For $\lambda < 1$ the origin is a regular point and the S_{μ_V} consists of one interval. For $\lambda > 1$ a gap opens up at the origin and the support consists two intervals. For the critical value $\lambda = 1$ the density of the equilibrium measure vanishes quadratically at the origin. We take the limit $n \to \infty$ but at the same time we let the gap open or close. That is, we let $n \to \infty$ and $\lambda_n \to 1$ simultaneously such that

$$n^{2/3}(\lambda_n - 1) \to s \in \mathbb{R}.$$

Then for some constants $c_1, c_2 > 0$ we have

(2.8)

$$\lim_{n\to\infty,\lambda_n\to 1} \frac{1}{(c_1 n)^{1/3}} K_n\left(x^* + \frac{x}{(c_1 n)^{1/3}}, x^* + \frac{y}{(c_1 n)^{1/3}}; \lambda_n\right) = K_{\mathrm{PII}}(x, y; c_2 s).$$

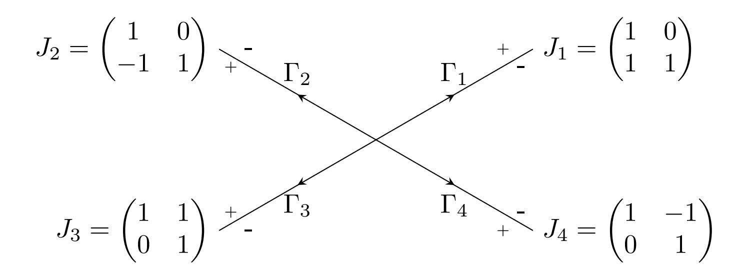

Figure 1: The jump contour Σ_Ψ in the complex ζ-plane and the constant jump matrices J_k on each of the rays Γ_k, $k = 1, \ldots, 4$.

Here $K_{\rm PII}(\cdot, \cdot; \nu)$ with $\nu \in \mathbb{R}$ is a family of kernels for which the description is more complicated than the limits in (2.6) and (2.7). It can be characterized in terms of a Lax pair for the Hastings-McLeod solution to the Painlevé II equation. Here we will treat the Riemann-Hilbert problem(= RH problem) characterization of the kernel. See [33] for more details on the Riemann-Hilbert approach to the Painlevé equations.

First we define the contour $\Sigma_\Psi = \Gamma_1 \cup \Gamma_2 \cup \Gamma_3 \cup \Gamma_4$, consisting of the rays

$$\Gamma_1 = e^{\pi i/6}\mathbb{R}^+, \quad \Gamma_2 = e^{5\pi i/6}\mathbb{R}^+, \quad \Gamma_3 = -\Gamma_1, \quad \Gamma_4 = -\Gamma_2.$$

All rays are oriented towards infinity. The orientation also allows us to provide each point of the contour with a + side lying at the left and a $-$ side lying at the right when traversing the contour according to its orientation.

RH problem 2.1. For $\nu \in \mathbb{R}$, we look for a 2×2 matrix-valued function $\Psi(\zeta; \nu)$ satisfying

(1) $\Psi(\zeta; \nu)$ is analytic for $\zeta \in \mathbb{C} \setminus \Sigma_\Psi$;

(2) $\Psi_+(\zeta; \nu) = \Psi_-(\zeta; \nu) J_k$, for $\zeta \in \Gamma_k$, $k = 1, \ldots, 4$. Here $\Psi_\pm$ stands for the limiting value of Ψ at the $\pm$ side of Γ_k and J_k is as in Figure 1.

(3) As $\zeta \to \infty$ we have

$$\Psi(\zeta; \nu) = \left(I + \mathcal{O}(\zeta^{-1})\right) \begin{pmatrix} e^{-i\frac{4}{3}\zeta^3 - i\nu\zeta} & 0 \\ 0 & e^{i\frac{4}{3}\zeta^3 + i\nu\zeta} \end{pmatrix};$$

(4) $\Psi(\zeta; \nu)$ is bounded near $\zeta = 0$.

This RH problem was introduced by Flaschka and Newell in [31]. They showed that from this RH problem one can retrieve the Hastings-McLeod solution for the Painlevé II equation. More precisely, define $q(\nu)$ by

$$q(\nu) = \lim_{\zeta \to \infty} \zeta \Psi_{12}(\zeta; \nu) e^{-i\frac{4}{3}\zeta^3 - i\nu\zeta},$$

where Ψ_{12} is the 12-entry of Ψ, then q is the unique solution to the Painlevé II equation

$$q''(\nu) = 2q(\nu)^3 + \nu q(\nu),$$

uniquely characterized by the asymptotic condition $q(\nu) = \mathrm{Ai}(\nu)(1 + o(1))$ as $\nu \to +\infty$. One can show that there exists a unique solution Ψ to RH problem 2.1 if and only if the Hastings-McLeod solution q has no pole at ν. Since it is known that this solution has no real poles [37], it follows that Ψ exists for all $\nu \in \mathbb{R}$. The kernel K_{PII} at the right-hand side of (2.8) is now given by

$$K_{\mathrm{PII}}(x, y; \nu) = \frac{1}{2\pi i(x-y)} \begin{pmatrix} 1 & -1 \end{pmatrix} \Psi^{-1}(y;\nu)\Psi(x;\nu) \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \tag{2.9}$$

where $\Psi(\zeta, \nu)$ is the unique solution to RH problem 2.1.

For interior singular point of higher order, $\rho(x) \sim (x - x^*)^{2m}$ the kernel is characterized by a RH problem associated to a special solution to the m-th member of the Painlevé II hierarchy.

2.3.2 Singular edge points

Near a singular endpoint we have similar limits for the kernel but where the Painlevé II equation is replaced by the Painlevé I equation. For example, in [16] it is proved that the singular endpoint with vanishing exponent 5/2 is related to the second member of the Painlevé I hierarchy. For the general exponent $m + 1/2$ related to the m-th member of the Painlevé I hierarchy see [14].

It is interesting to note that is not possible to obtain a singular edge point with an exponent of 3/2 in the Hermitian one matrix model. However, by adjusting the model and considering orthogonal polynomials in the complex plane, a vanishing exponent of 3/2 can be realized [8, 24, 32] and this singular case is related to the Painlevé I equation. However, there is no probabilistic interpretation for this situation.

3 Two matrix model

In the Hermitian two matrix model we consider the probability measure on the space of couples (M_1, M_2) of $n \times n$ Hermitian matrices given by

$$\frac{1}{Z_n^{2M}} \exp\left(-n \operatorname{Tr}\left(V(M_1) + W(M_2) - \tau M_1 M_2\right)\right) \mathrm{d}M_1 \mathrm{d}M_2. \tag{3.1}$$

Here V and W are two polynomials of even degree and positive leading coefficients, Z_n^{2M} is a normalizing constant and $\tau > 0$ is called the coupling constant. Note that if $\tau = 0$, the probability measure factorizes and M_1 and M_2 are independent matrices taken randomly from (2.1) with potential V and W respectively.

We will be concerned with the asymptotic behavior of the eigenvalues of M_1 and M_2 as $n \to \infty$. In this section we will discuss some general characteristics of the two matrix model and in particular the relation to certain biorthogonal polynomials.

3.1 Master loop equation

An important motivation for studying the two matrix model is that there is strong evidence that it generates a wide class of singular points that can not appear in the one matrix model.

By formal calculations one can show that the limiting eigenvalue distributions are characterized by an algebraic curve, which is also often referred to as the master loop equation and is the equivalent of (2.4) for the two matrix model. To this end, define the following functions

$$\begin{aligned} Y_n(x) &= V'(x) - \frac{1}{n}\mathbb{E}_n^{2M}\left[\operatorname{Tr}\frac{1}{x-M_1}\right] \\ X_n(y) &= W'(y) - \frac{1}{n}\mathbb{E}_n^{2M}\left[\operatorname{Tr}\frac{1}{y-M_2}\right] \\ P_n(x,y) &= \frac{1}{n}\mathbb{E}_n^{2M}\left[\operatorname{Tr}\frac{V'(x)-V'(M_1)}{x-M_1}\frac{W'(y)-W'(M_2)}{y-M_2}\right] \\ E_n(x,y) &= \tau(V'(x)-\tau y)(W'(y)-\tau x) - P_n(x,y) + \tau^2, \end{aligned}$$

where $\mathbb{E}_n^{2M}$ stand for the expectation with respect to (3.1). The conjecture is that these functions have expansions in $1/n^2$, i.e.

$$Y_n = Y^{(0)} + \frac{1}{n^2}Y^{(1)} + \cdots,$$

and similarly for X_n, P_n and E_n. Moreover, the various terms in the expansion satisfy a recursive system of equations that are called the loop equations [29] (for a survey on the formal analysis of matrix models using loop equations see for example [52] and the reference therein). The first of the loop equations, also called the master loop equation, reads

$$E^{(0)}\left(x, \tfrac{1}{\tau}Y^{(0)}(x)\right) = E^{(0)}\left(\tfrac{1}{\tau}X^{(0)}(y), y\right) = 0, \tag{3.2}$$

which is to be interpreted as the equivalent of (2.4) for the two matrix model.

The function $E^{(0)}$ is a polynomial of degree $\deg V$ in x and degree $\deg W$ in y, whereas in the one matrix model (2.4) always has degree 2 in one of the variables. Under special choices of parameters the curve defined by (3.2) has interesting singular points that cannot occur in the one matrix model [17]. For example, it is possible to obtain a limiting measure where the density vanishes with a vanishing exponent p/q. Near these points we expect to obtain new interesting scaling limits. We recall that the only possible singular cases for the curve (2.4) corresponding to the one matrix model, are the ones listed in Section 2.3 (and hence $q = 2$).

At this point we want to emphasize that (3.2) is derived in a formal way. In [35] it was proved that the empirical eigenvalue distributions of M_1 and M_2 have weak limit almost surely. This means in particular that Y_n and X_n have limits, but to the best of my knowledge there is no rigorous proof of an $1/n^2$ expansion or of (3.2).

3.2 Biorthogonal polynomials

The important feature of the one matrix model that made it possible to analyze it explicitly, is that it can be integrated in terms of orthogonal polynomials. In the two matrix model there is a similar structure. Let $(p_{j,n})_j$ and $(q_{k,n})_k$ be two sequences of monic polynomials, with $\deg p_{j,n} = j$ and $\deg q_{k,n} = k$, such that they satisfy the biorthogonality relation

$$\iint_{\mathbb{R}^2} p_{j,n}(x) q_{k,n}(y) \mathrm{e}^{-n(V(x)+W(y)-\tau xy))}\, \mathrm{d}x\mathrm{d}y = h_{k,n}^2 \delta_{jk},$$

for certain constants $h_{k,n}^2$. Since the orthogonality is not with respect to a Hermitian inner product, it is not a priori clear that the polynomials exists. In [28] it was proved that they do exist, are unique and have properties that are typical for orthogonal polynomials. They have real and simple zeros [28] and the zeros satisfy an interlacing property [23]. Their integrable structure has been extensively explored in [3, 4, 5].

As in the one matrix model (2.5), the marginal densities or correlation function for the eigenvalues have a determinantal structure. To this end, we define

$$P_{j,n}(y) = \int_{\mathbb{R}} p_{j,n}(x) \mathrm{e}^{-n(W(y)+V(x)-\tau xy)} \mathrm{d}x,$$
$$Q_{k,n}(x) = \int_{\mathbb{R}} q_{j,n}(y) \mathrm{e}^{-n(W(y)+V(x)-\tau xy)} \mathrm{d}y,$$

and the following four kernels

$$K_{11}^{(n)}(x_1, x_2) = \sum_{k=0}^{n-1} \frac{1}{h_{k,n}^2} p_{k,n}(x_1) Q_{k,n}(x_2), \tag{3.3}$$
$$K_{12}^{(n)}(x, y) = \sum_{k=0}^{n-1} \frac{1}{h_{k,n}^2} p_{k,n}(x) q_{k,n}(y),$$
$$K_{21}^{(n)}(y, x) = \sum_{k=0}^{n-1} \frac{1}{h_{k,n}^2} P_{k,n}(y) Q_{k,n}(x) - \mathrm{e}^{-n(V(x)+W(y)-\tau xy)},$$
$$K_{22}^{(n)}(y_1, y_2) = \sum_{k=0}^{n-1} \frac{1}{h_{k,n}^2} P_{k,n}(y_1) q_{k,n}(y_2).$$

Then by the Eynard-Mehta theorem [30] the marginal densities of the point process given by the eigenvalues of M_1 and M_2 have the following structure

$$\underbrace{\int \cdots \int}_{n-k+n-l \text{ times}} \mathcal{P}(x_1,\ldots,x_n,y_1,\ldots,y_n)\mathrm{d}x_{k+1}\cdots \mathrm{d}x_n \mathrm{d}y_{l+1}\cdots \mathrm{d}y_n$$

$$= \frac{(n-k)!(n-l)!}{n!^2} \det \begin{pmatrix} \left(K_{11}^{(n)}(x_i,x_j)\right)_{i,j=1}^{k} & \left(K_{12}^{(n)}(x_i,y_j)\right)_{i,j=1}^{k,l} \\ \left(K_{21}^{(n)}(y_i,x_j)\right)_{i,j=1}^{l,k} & \left(K_{22}^{(n)}(y_i,y_j)\right)_{i,j=1}^{l} \end{pmatrix},$$

for $k,l = 1,\ldots,n$. For example, if we average over M_2 then we see that the eigenvalues of M_1 form a determinantal point process with kernel $K_{11}^{(n)}$ given in (3.3). To find the asymptotic behavior of the eigenavalues and the limiting local correlations, it suffices to compute the asymptotic behavior of the kernels $K_{ij}^{(n)}$.

3.3 Riemann-Hilbert problem(s)

The asymptotic behavior of orthogonal polynomials that appear in the one matrix model can be effectively computed using the RH problem approach (see for example [44] for a discussion). It is therefore natural to search for a characterization of the biorthogonal polynomials in terms of a RH problem. Several such characterizations exist [5, 28, 42, 43]. Here we will discuss the RH problem from [43] as this was the starting point for the analysis in [22, 25, 26, 49]. It should be noted that this RH problem is equivalent to the RH problem in [5].

Write $d_W = \deg W$ and define the functions

$$w_{j,n}(x) = \int_{\mathbb{R}} y^j \mathrm{e}^{-n(W(y)+V(x)-\tau xy)}\mathrm{d}y, \qquad j = 0,1,\ldots d_W - 2.$$

Then the kernel $K_{11}^{(n)}$ in (3.3) can be characterized by the following RH problem.

RH problem 3.1. We look for a $d_W \times d_W$ matrix valued function Y such that

1. Y is analytic in $\mathbb{C} \setminus \mathbb{R}$:
2. $Y_+(x) = Y_-(x) \begin{pmatrix} 1 & w_{0,n}(x) & \cdots & w_{d_W-1,n}(x) \\ & \ddots & & 0 \\ & & \ddots & \\ 0 & & & 1 \end{pmatrix}$ for $x \in \mathbb{R}$,
3. $Y(z) = (I + \mathcal{O}(1/z))\,\mathrm{diag}(z^n, z^{-n_0}, \ldots, z^{-n_{d_W-2}})$ as $z \to \infty$. where n_j is the integer part of $(n + d_W - j - 2)/(d_W - 1)$.

There exists a unique solution to the RH problem 3.1 which can be expressed in terms of the biorthogonal polynomials [43]. In particular we have $Y_{11}(z) = p_{n,n}(z)$ and

$$K_{11}^{(n)}(x_1,x_2) = \tfrac{1}{2\pi\mathrm{i}(x_1-x_2)} \begin{pmatrix} 0 & w_{0,n}(x_2) & \cdots & w_{d_w-2}(x_2) \end{pmatrix} Y_+^{-1}(x_2) Y_+(x_1) \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

For the polynomials $q_{n,n}$ and the kernel $K_{22}^{(n)}$ a similar RH problem holds.

The strategy for analyzing the two matrix model, is to perform a steepest descent analysis on the RH problem as $n \to \infty$. For the general situation this is still an open problem. However, for the special case of quartic W we recently analyzed the asymptotic behavior in a series of papers that we will discuss in the next section.

4 Two matrix model with a quartic potential

In this section we will discuss the two matrix model (3.1) for the following special choice of potentials

$$V \text{ even} \qquad \text{and} \qquad W(y) = \frac{1}{4}y^4 + \frac{\alpha}{2}y^2. \tag{4.1}$$

In [25, 26, 49] we performed the steepest descent analysis for RH problem 3.1 for the kernel $K_{11}^{(n)}$ in (3.3) that characterizes the eigenvalues of M_1. To this end, we used a vector equilibrium problem that we will discuss in Section 4.1 and 4.2. In Section 4.3–4.5 we further assume that $V(x) = \frac{1}{2}x^2$ and identify all possible singular cases that can occur and present a phase diagram [23] in Section 4.3. In particular, there is a new type of singular point around we obtain a new kernel [22] which we discuss in Section 4.4 and 4.5.

4.1 Vector equilibrium problem

Let us assume that we are in the situation (4.1). The key ingredient in the asymptotic analysis of [25, 26, 49] is that we found a coulomb gas interpretation for the limiting distribution of the eigenvalues of M_1 that we will now describe. See also [27] for an alternative discussion.

For two probability measures μ and ν we define the mutual logarithmic energy $I(\mu,\nu)$ and the logarithmic energy $I(\mu)$ by [53]

$$I(\mu,\nu) = \iint \log \frac{1}{|x-y|}\, \mathrm{d}\mu(x)\mathrm{d}\nu(y), \qquad I(\mu) = I(\mu,\mu).$$

The equilibrium problem is to minimize the energy functional $E(\nu_1,\nu_2,\nu_3)$ defined by

$$\begin{aligned} E(\nu_1,\nu_2,\nu_3) = \sum_{j=1}^{3} I(\nu_j) - \sum_{j=1}^{2} I(\nu_j,\nu_{j+1}) \\ + \int V_1(x)\, \mathrm{d}\nu_1(x) + \int V_3(x)\, \mathrm{d}\nu_3(x), \end{aligned} \tag{4.2}$$

among all vectors of measure (ν_1,ν_2,ν_3) satisfying the following conditions:

1. ν_1 is a measure on $\mathbb{R}$ with total mass 1.
2. ν_2 is a measure on $\mathrm{i}\mathbb{R}$ with total mass $2/3$.

3. ν_3 is a measure on $\mathbb{R}$ with total mass $1/3$.
4. $\nu_2 \leq \sigma_2$.

We need to clarify the external fields V_1 and V_3 acting on μ_1 and μ_3, and the constraint σ_2 on μ_2. To this end, note that the function

$$s \mapsto W(s) - \tau x s$$

with W as in (4.1), has a global minimum attained at some point $s = s_1(x)$. Moreover, if $\alpha < 0$ and $|x| \leq \frac{2}{\tau}(-\alpha/3)^{3/2}$ the function has another local minimum at some point $s_2(x)$ and a local maximum at some point $s_3(x)$.

The external field V_1 in (4.2) is defined as

$$V_1(x) = V(x) + W(s_1(x)) - \tau x s_1(x).$$

Moreover, the external field V_3 is defined

$$V_3(x) = \begin{cases} W(s_3(x)) - \tau x s_3(x) - (W(s_2(x)) - \tau x s_2(x)), & \text{if } s_{2,3}(x) \text{ exist,} \\ 0, & \text{otherwise.} \end{cases}$$

Finally, the constraint σ_2 is a measure that is absolutely continuous with respect to the Lebesgue measure with density

$$\frac{\mathrm{d}\sigma_2(z)}{|\mathrm{d}z|} = \frac{\tau}{\pi} \max_{s^3+\alpha s = \tau z} \operatorname{Re} s, \qquad z \in \mathrm{i}\mathbb{R}.$$

The following theorem was proved in [25] for the case $\alpha = 0$ and in [26] for general α. See also [36].

Theorem 4.1. *Let V and W as in* (4.1)*. The energy functional E defined in* (4.2) *has a unique minimizer (μ_1, μ_2, μ_2) among all vectors of measures satisfying the conditions listed below* (4.2)*.*

The support of the measures in the unique minimizer (μ_1, μ_2, μ_3) have the following structure

$$\begin{aligned} S(\mu_1) &= \cup_{j=1}^{N} [a_j, b_j] \\ S(\sigma - \mu_2) &= \mathrm{i}\mathbb{R} \setminus (-\mathrm{i}c_2, \mathrm{i}c_2), \\ S(\mu_3) &= \mathbb{R} \setminus (-c_3, c_3) \end{aligned}$$

for some $c_1, c_2 > 0$ and $a_1 < b_1 < a_2 < \ldots < b_N$ and $N \in \mathbb{N}$. All measures are absolutely continuous with analytic densities (possibly except at the origin). Moreover, if $c_2 > 0$ then the density of $\sigma_2 - \mu_2$ vanishes as a square root at $\pm \mathrm{i}c_2$. Similarly for $c_3 > 0$ and μ_3.

Away from the origin, the measure μ_1 in the minimizer has the same behavior that one finds for the equilibrium measure in the one matrix model. Generically its density is strictly positive in the interior of the support, it vanishes as a square root at the endpoints and the variational inequality is strict. If we are in this situation and on top of that we have that in case $0 \in S(\sigma - \mu_2)$ or $0 \in S(\mu_3)$ then the density for that measure is strictly positive at the origin, then we say that (V, W, τ) is regular. The following result is Theorem 1.4 in [26].

Theorem 4.2. *Let (V, W, τ) be regular. Then, as $n \to \infty$ and $n \equiv 0 \mod 3$, the mean eigenvalue distribution of M_1 converges weakly to the first component μ_1 of the minimizer (μ_1, μ_2, μ_3) of the vector equilibrium problem.*

We strongly believe that it holds also in all the singular situations and that we can drop the condition $n \equiv 0 \mod 3$ that we needed for technical reasons.

The measure μ_1 describes the limiting behavior for the eigenvalues on the global scale and the natural question rises what happens on the local scale. In the regular case, the kernel $K_{11}^{(n)}$ converges to the sine kernel in the bulk and Airy kernel at the edge points as in (2.6) and (2.7). Away from he origin, the measure μ_1 can have the same singular points as in the one matrix model and the kernel $K_{11}^{(n)}$ has the corresponding limiting behavior. However, due to the more complicated interaction with the measure μ_2 and μ_3, at the origin new critical phenomena may take place which we will explore further in Sections 4.3–4.5.

4.2 Associated Riemann surface

At first sight, the characterization of the limiting eigenvalue distribution in terms of a vector equilibrium problem appears to be quite different from the master loop equation (3.2). However, the solution to the vector equilibrium problem can be described by an algebraic curve as we will now show.

Let $\mathcal{R} = \bigcup_{j=1}^{4} \mathcal{R}_j$ be where

$$\begin{aligned}
\mathcal{R}_1 &= \overline{\mathbb{C}} \setminus S(\mu_1) \\
\mathcal{R}_2 &= \mathbb{C} \setminus (S(\mu_1) \cup S(\sigma_2 - \mu_2) \\
\mathcal{R}_3 &= \mathbb{C} \setminus (S(\sigma_2 - \mu_2) \cup S(\mu_3)) \\
\mathcal{R}_4 &= \mathbb{C} \setminus S(\mu_3)
\end{aligned}$$

and $\mathcal{R}_j$ is connected to $\mathcal{R}_{j+1}$ in the usual crosswise manner. The following result follows from the variational conditions for the equilibrium problem and is Proposition 4.8 in [26].

Proposition 4.3. *The function $\xi : \mathcal{R}_1 \to \mathbb{C}$ defined by*

$$\xi(z) = V'(z) - \int \frac{1}{z-s} \, \mathrm{d}\mu_1(s), \tag{4.3}$$

extends to a meromorphic function on $\mathcal{R}$, with a pole at infinity of degree $\deg V - 1$ on the sheet $\mathcal{R}_1$ and a simple pole at infinity at the other sheets.

From the last result it follows that the function ξ is described by an algebraic curve

$$\xi^4 + P_3(x)\xi^3 + P_2(x)\xi^2 + P_1(x)\xi + P_0(x) = 0$$

for certain polynomials $P_j(x)$. Moreover, the restriction of ξ to the first sheet $\mathcal{R}_1$ plays the role of $Y^{(0)}$ in (3.2).

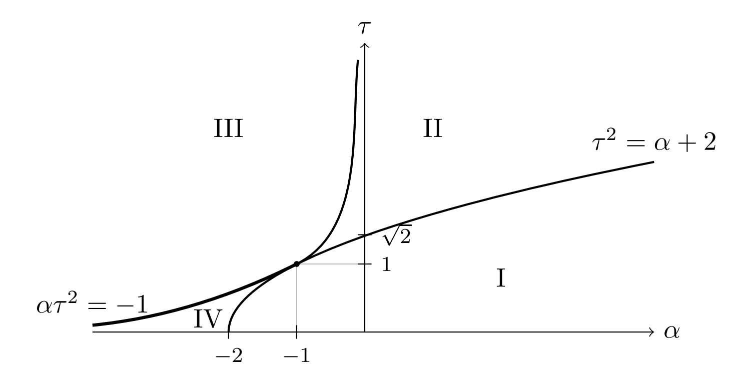

Figure 2: The phase diagram in the $\alpha\tau$-plane: the critical curves $\tau^2 = \alpha + 2$ and $\alpha\tau^2 = -1$ separate the four cases.

4.3 Phase diagram for quartic/quadratic case

Let us consider the special situation

$$V(x) = \tfrac{1}{2}x^2, \qquad \text{and} \qquad W(y) = \tfrac{1}{4}y^4 + \tfrac{\alpha}{2}y^2, \tag{4.4}$$

and discuss the structure of the vector (μ_1, μ_2, μ_3) minimizing the energy E and the associated surface $\mathcal{R}$. For this situation an alternative and perhaps more direct derivation of the equilibrium problem can be found in [23].

In this special situation we also have that μ_1 is supported on one or two intervals. Hence there exists $a, c_1, c_2, c_3 \geq 0$ such

$$\begin{aligned} S(\mu_1) &= [-a, a] \setminus (-c_1, c_1), \\ S(\sigma_2 - \mu_2) &= \mathrm{i}\mathbb{R} \setminus (-\mathrm{i}c_2, \mathrm{i}c_2), \\ S(\mu_3) &= \mathbb{R} \setminus (-c_3, c_3). \end{aligned}$$

If $c_1 = 0$ the μ_1 is supported on one interval and if $c_1 > 0$ it is supported on two intervals. We now distinguish four different cases

Case I	$c_1, c_3 = 0$ and $c_2 > 0$
Case II	$c_3 = 0$ and $c_1, c_2 > 0$.
Case III	$c_2 = 0$ and $c_1, c_3 > 0$
Case IV	$c_1 = 0$ and $c_2, c_3 > 0$.

In Figure 4 we showed the sheet structure of the associated Riemann surface $\mathcal{R}$ in each of the four case. Depending on the values of τ and α we are in one of these four cases (or a transition from one to the other).

In Figure 2 we plotted an $\alpha\tau$-phase diagram. The $\alpha\tau$-plane is separated into four regions by the curves $\tau^2 = 2 + \alpha$ and $\alpha\tau = -1$ and each region corresponds to a particular case. As long as we are not on one of the two separating curves, we are in the generic situation and the local correlation for the eigenvalues of M_1

are given by the sine kernel at the bulk and Airy kernel at the edge. However, if we pass one of the separating curves there is a transition and at the origin the local correlations may have different limits. We will now discuss the various transitions but leave the multicritical situation $(\alpha,\tau)=(-1,1)$ to the next section. See also Figure 5 for the Riemann surface $\mathcal{R}$ at the points of transition.

Case I $\leftrightarrow$ Case II. In this transition the support $S(\mu_1)$ splits from one interval into two intervals. At the splitting point, the density of μ_1 vanishes quadratically. The situation is the same as in the one matrix model and again the local correlations are governed by the kernel K_{PII} as given in (2.9).

Case IV$\leftrightarrow$ Case I. Here we see that there is a transition in the support of $S(\mu_3)$. In Case IV there is a gap in the support $S(\mu_3)$ that closes at the point of transition to dissapear in Case I. In fact, the transition is similar to the transition from Case I to Case II, but now it concerns the measure μ_3. As it turns out, it does not have an effect on the eigenvalues of M_1.

Case III $\leftrightarrow$ Case IV. When we travel from Case III to Case IV the two intervals in the support of $S(\mu_1)$ merge to one interval, but simultaneously a gap in the support of $S(\sigma_2-\mu_2)$ opens up. The origin is a branch point connecting the first three sheets of the Riemann surface. This situation cannot happen in the case of the one matrix model. However, it has appeared before in the one matrix model with external source [9]. The local correlation in this case are given by the Pearcey kernel

$$K_{\mathrm{Pe}}(x,y;s)=\frac{1}{(2\pi \mathrm{i})^2}\int_{\mathcal{C}}\int_{-\mathrm{i}\infty}^{\infty}\mathrm{e}^{\frac{1}{4}w^4-\frac{s}{2}w^2+xw-\frac{1}{4}z^4+\frac{s}{2}z^2-yw}\,\frac{\mathrm{d}z\mathrm{d}w}{z-w},\tag{4.5}$$

where $\mathcal{C}$ is a contour that consists of two rays from $\pm\infty\mathrm{e}^{\mathrm{i}\pi/4}$ to 0 together with two rays from 0 to $\pm\infty\mathrm{e}^{-\mathrm{i}\pi/4}$. See also [11, 12, 51, 57].

Case II $\leftrightarrow$ Case III. The situation is very similar to the transition from Case III to Case IV but now the origin is a branch point connecting the three sheets $\mathcal{R}_2,\mathcal{R}_3$ and $\mathcal{R}_4$. As in the transition from Case IV to Case I it does not effect the eigenvalue distribution of M_1.

4.4 Critical point

We now deal with the multicritical point $(\alpha,\tau)=(-1,1)$. In this case, the origin connects all four sheets of the Riemann surface $\mathcal{R}$, see also the picture at the bottom of Figure 5. In this case the function ξ in (4.3) is given by the algebraic curve

$$\xi^4-x\xi^3+x^2=0$$

and the limiting eigenvalue distribution vanishes with a square root near the origin which is at the *interior* of the support. In [22] we characterized the limiting kernel which we will now discuss. To this end we first need the following RH problem.

RH problem 4.4. Let $s,t\in\mathbb{R}$. We search for a 4×4 matrix-valued function $M(\zeta)$ satisfying

(1) M is analytic for $\zeta \in \mathbb{C} \setminus \Sigma_M$;

(2) $M_+(\zeta) = M_-(\zeta) J_k$, for $\zeta \in \Gamma_k$, $k = 0, \ldots, 9$;

(3) As $\zeta \to \infty$ with $\zeta \in \mathbb{C} \setminus \Sigma_M$ we have

$$(4.6) \quad M(\zeta) = \left(I + \mathcal{O}(\zeta^{-1})\right) \operatorname{diag}\left((-\zeta)^{-1/4}, \zeta^{-1/4}, (-\zeta)^{1/4}, \zeta^{1/4}\right)$$
$$\times \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & -i & 0 \\ 0 & 1 & 0 & i \\ -i & 0 & 1 & 0 \\ 0 & i & 0 & 1 \end{pmatrix} \operatorname{diag}\left(e^{-\frac{2}{3}(-\zeta)^{3/2} - 2s(-\zeta)^{1/2} + t\zeta}, e^{-\frac{2}{3}\zeta^{3/2} - 2s\zeta^{1/2} - t\zeta},\right.$$
$$\left. e^{\frac{2}{3}(-\zeta)^{3/2} + 2s(-\zeta)^{1/2} + t\zeta}, e^{\frac{2}{3}\zeta^{3/2} + 2s\zeta^{1/2} - t\zeta}\right).$$

(4) $M(\zeta)$ is bounded near $\zeta = 0$.

The fractional powers in $\zeta \mapsto \zeta^{3/2}$, $\zeta \mapsto \zeta^{1/2}$ and $\zeta \mapsto \zeta^{\pm 1/4}$ are chosen such that these maps are analytic in $\mathbb{C} \setminus (-\infty, 0]$ and take positive values on the positive part of the real line. The fractional powers in $\zeta \mapsto (-\zeta)^{3/2}$, $\zeta \mapsto (-\zeta)^{1/2}$ and $\zeta \mapsto (-\zeta)^{\pm 1/4}$ are chosen such that these maps are analytic in $\mathbb{C} \setminus [0, \infty)$ and take positive values on the negative part of the real line.

The contour Σ_M is shown in Figure 3 and consists of 10 rays emanating from the origin. The function $M(\zeta)$ makes constant jumps J_k on each of the rays Γ_k. These rays are determined by two angles φ_1 and φ_2 satisfying $0 < \varphi_1 < \varphi_2 < \pi/2$. The half-lines Γ_k, $k = 0, \ldots, 9$, are defined by

$$\Gamma_0 = \mathbb{R}^+, \qquad \Gamma_1 = e^{i\varphi_1}\mathbb{R}^+, \qquad \Gamma_2 = e^{i\varphi_2}\mathbb{R}^+,$$
$$\Gamma_3 = e^{i(\pi - \varphi_2)}\mathbb{R}^+, \qquad \Gamma_5 = e^{i(\pi - \varphi_1)}\mathbb{R}^+,$$

and $\Gamma_{5+k} = -\Gamma_k$, for $k = 0, \ldots, 4$. All rays are oriented towards infinity.

For $s, t \in \mathbb{R}$ the solution to the RH problem exist and is unique [22, Th. 2.2]. Moreover, the RH problem is related to the Hastings-McLeod solution for the Painlevé II equation. Indeed, by rewriting $I + \mathcal{O}(1/\zeta)) = I + M^{(1)}/\zeta + \ldots$ in (4.6) we have

$$\left(M^{(1)}\right)_{1,4} = i 2^{-1/3} q\left(2^{2/3}(2s - t^2)\right),$$

where the left-hand side is the 14 entry of $M^{(1)}$ and q stands for the Hastings-McLeod solution. In fact, by taking derivatives with respect to ζ and the parameters s, t we can obtain from the RH problem a system of first order differential equations for M for which the Painlevé II equation appears as the compatibility condition [21, 22].

We now define K_{cr} by

$$K_{\mathrm{cr}}(u, v; s, t) = \frac{1}{2\pi i(u - v)} \begin{pmatrix} 1 & 1 & 0 & 0 \end{pmatrix} M(\mathrm{i}v; s, t)^T M(\mathrm{i}u; s, t)^{-T} \begin{pmatrix} -1 \\ 1 \\ 0 \\ 0 \end{pmatrix}.$$

$$\Gamma_3:\ \begin{pmatrix}1&1&0&0\\0&1&0&0\\0&0&1&0\\0&0&-1&1\end{pmatrix} \qquad \Gamma_2:\ \begin{pmatrix}1&0&0&0\\-1&1&0&0\\0&0&1&1\\0&0&0&1\end{pmatrix}$$

$$\Gamma_4:\ \begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&-1&0&1\end{pmatrix} \qquad \Gamma_1:\ \begin{pmatrix}1&0&0&0\\0&1&0&0\\1&0&1&0\\0&0&0&1\end{pmatrix}$$

$$\Gamma_5:\ \begin{pmatrix}1&0&0&0\\0&0&0&-1\\0&0&1&0\\0&1&0&0\end{pmatrix} \qquad \Gamma_0:\ \begin{pmatrix}0&0&1&0\\0&1&0&0\\-1&0&0&0\\0&0&0&1\end{pmatrix}$$

$$\Gamma_6:\ \begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&-1&0&1\end{pmatrix} \qquad \Gamma_9:\ \begin{pmatrix}1&0&0&0\\0&1&0&0\\1&0&1&0\\0&0&0&1\end{pmatrix}$$

$$\Gamma_7:\ \begin{pmatrix}1&-1&0&0\\0&1&0&0\\0&0&1&0\\0&0&1&1\end{pmatrix} \qquad \Gamma_8:\ \begin{pmatrix}1&0&0&0\\1&1&0&0\\0&0&1&-1\\0&0&0&1\end{pmatrix}$$

Figure 3: The jump contour Σ_M in the complex ζ-plane and the constant jump matrices J_k on each of the rays Γ_k, $k = 0, \ldots, 9$.

where M^T stands for the transpose of M and M^{-T} for the inverse transpose. The following theorem is the main result in [22].

Theorem 4.5. *Let V and W be as in* (4.4) *and set*

$$\begin{pmatrix}\alpha\\ \tau\end{pmatrix} = \begin{pmatrix}-1\\ 1\end{pmatrix} + an^{-1/3}\begin{pmatrix}2\\ 1\end{pmatrix} + bn^{-2/3}\begin{pmatrix}-1\\ 2\end{pmatrix},$$

for $a, b \in \mathbb{R}$. Then for $n \to \infty$ and $n \equiv 0 \mod 6$, and $K_{11}^{(n)}$ as in (3.3) *we have*

$$\lim_{n\to\infty} \frac{1}{n^{2/3}} K_{11}^{(n)}\left(\frac{u}{n^{2/3}}, \frac{v}{n^{2/3}}\right) = K_{\mathrm{cr}}\left(u, v; \tfrac{1}{4}(a^2 - 5b), -a\right), \tag{4.7}$$

uniformly for u, v in compact subsets of $\mathbb{R}$.

It is interesting that RH problem 4.4 with $t = 0$ appeared before [21] in the characterization of the kernel near a tacnode singularity in a model of non-intersecting brownian paths (see also [1, 41]) for alternative characterizations). The apparent reason for this is that also in the case of the tacnode singularity, the critical measure vanishes as a square root near an interior point. Nevertheless, the kernel describing the tacnode singularity is constructed in a different way out of the RH problem. In [22] we proved that, perhaps somewhat surprisingly, the two kernels define essentially different processes.

4.5 Reductions of the new kernel

There is a a certain hierarchy in the limiting kernels that we have discussed so far. Let us denote the sine and Airy kernel (i.e. the right-hand sides of (2.6) and (2.7)) by K_{sine} and K_{Ai}. We also recall the definition of K_{PII} and K_{Pe} in (2.9) and (4.5). The kernel K_{cr} is on top of the hierarchy, in the sense that the four other kernels are limit points for K_{cr}. For instance, from the phase diagram in Figure 2 we see that if we walk from the critical point $(\alpha,\tau)=(-1,1)$ to the right along the curve $\tau^2=2+\alpha$, we end up in the in the critical situation described by the kernel K_{PII}. In [22] we proved that K_{PII} is a limit point of K_{cr} in the following way. There exists a function h such that

$$\lim_{a\to+\infty} 2^{\frac{5}{3}} a \frac{h(x,a)}{h(y,a)} K_{\mathrm{cr}}\left(2^{\frac{5}{3}}ax, 2^{\frac{5}{3}}ay; \frac{a^2}{2}, -a\left(1-\frac{\sigma}{a^2}\right)\right) = K_{\mathrm{PII}}(x,y;2^{\frac{5}{3}}\sigma),$$

uniformly for x,y in compact sets. (Note that as the correlation functions are determinantal they are invariant under conjugation of the kernel by the function h and the point process is not changed)

If we walk from $(\alpha,\tau)=(-1,1)$ along the curve $\tau=-1/\alpha$ in the phase diagram, then we expect to obtain the Pearcey kernel as a limit. In a recent paper [34] the authors proved that

$$\lim_{a\to+\infty} \frac{1}{\sqrt{2}a^{\frac{1}{4}}} K_{\mathrm{cr}}\left(\frac{x}{\sqrt{2}a^{\frac{1}{4}}}, \frac{y}{\sqrt{2}a^{\frac{1}{4}}}, -\tfrac{1}{2}a^2, a\left(1-\frac{\sigma}{2a^{\frac{3}{2}}}\right)\right) = K_{\mathrm{Pe}}(x,y;\sigma), \tag{4.8}$$

uniformly for x,y in compact subsets.

Finally, we note that the transitions $K_{\mathrm{Pe}}\to K_{\mathrm{Ai}}$ and $K_{\mathrm{Ai}}\to K_{\mathrm{Sine}}$ can for example be proved by classical steepest descent methods on the integral representations for the Airy and Pearcey functions. Moreover, the transition $K_{\mathrm{PII}}\to K_{\mathrm{Ai}}$ can be found using steepest descent techniques on the RH problem 2.1 for K_{PII}.

5 Singular points in one matrix models revisited

Now that we have characterized the correlations for the eigenvalues of M_1 it is natural to ask about the eigenvalues of M_2, especially for the multi-critical point in the quartic/quadratic case. We will now answer this question in a general fashion and show that the multi-critical point discussed in Section 4 can be embedded into a larger class for which a rigorous treatment may be within reach.

First note in case

$$V(x)=\tfrac{1}{2}x^2 \text{ and } W \text{ arbitrary,}$$

we can complete the square and rewrite (3.1) as

$$\frac{1}{Z_n^{2M}} \exp\left(-n \operatorname{Tr}\left(\tfrac{1}{2}(M_1-\tau M_2)^2 + W(M_2) - \tfrac{1}{2}\tau^2 M_2\right)\right) \mathrm{d}M_1\mathrm{d}M_2. \tag{5.1}$$

Hence the matrices $M_1 - \tau M_2$ and M_2 are independent matrices taken randomly from the GUE (=Gaussian Unitary Ensemble) and the one matrix model (2.1) with potential

$$W_{\text{eff}}(y) = W(y) - \tfrac{1}{2}\tau^2 y^2.$$

Moreover, by writing the matrix M_1 as $M_1 = (M_1 - \tau M_2) + \tau M_2$, we see that M_1 is a linear combination of two random matrices taken independently from the GUE and the one matrix model (2.1) with potential W_{eff} respectively.

It is also important to note that in this situation the spectral curve (3.2) can also be computed in a fairly explicit way,

$$\tau(x - \tau\xi)(W'_{\text{eff}}(\xi) + \tau^2\xi - \tau x) - Q(\xi) = 0, \tag{5.2}$$

where Q is the polynomial

$$Q(\xi) = \int \frac{W'_{\text{eff}}(\xi) - W'_{\text{eff}}(t)}{\xi - t} \mathrm{d}\mu_{W_{\text{eff}}}(t),$$

and $\mu_{W_{\text{eff}}}$ is the equilibrium problem measure minimizing (2.3) with potential W_{eff}. We recall that there is no proof that (5.2) indeed characterizes the limiting eigenvalue distribution of the matrix M_1, but we are free to use it as an ansatz in a RH analysis and prove this fact a posteriori. This may be a good starting point of dealing with some particular interesting examples, some of which we will now discuss.

Let us proceed by choosing the parameters in the potential W so that W_{eff} does not depend on τ and consider the family of random matrices

$$M(\tau) = M_{\text{GUE}} + \tau M_{W_{\text{eff}}}$$

parametrized by τ. Note that $(\frac{1}{1+\tau}M(\tau))_\tau$ interpolates between M_{GUE} for $\tau = 0$ and $M_{W_{\text{eff}}}$ for $\tau \to \infty$. Let us also assume that W_{eff} leads to an equilibrium measure $\mu_{W_{\text{eff}}}$ for which the density vanishes with exponent $2m$ at the origin. Then on the local scale we expect to see a transition from the sine kernel to the kernel associated to the singular interior point (related to the Painlevé II hierarchy).

To see how this transition comes about we rewrite (5.2) to

$$\left(\tau(x - \tau\xi) - \frac{1}{2}(W'_{\text{eff}}(\xi)\right)^2 = \tfrac{1}{4}W'_{\text{eff}}(\xi)^2 - Q(\xi) = -\xi^{4m}(c + \mathcal{O}(\xi)),$$

as $\xi \to 0$, for some positive constant $c > 0$. Set $\tau_{\text{cr}} = \sqrt{-W''_{\text{eff}}(0)/2}$. If $\tau \neq \tau_{\text{cr}}$ then for $x = 0$ we find that $\xi = 0$ is a double solution and we have a singular point that connects two sheets of the Riemann surface. If the point is on the physical sheet $\mathcal{R}_1$ then the local correlations are given by the same kernel as we have for $M_{W_{\text{eff}}}$. In case $\tau = \tau_{cr}$ then for $x = 0$ the solution $\xi = 0$ is of multiplicity at least four (in case $m = 1$) or at least six (in case $m \geq 2$) and hence the singular point connects several sheets. Here we expect a more

complicated kernel, characterized by a RH problem that has the same size as the number of sheets involved.

Concluding, by adding an independent GUE matrix to a matrix taken randomly from a one matrix model with a singular interior point, we can construct higher order critical phenomena. It is an interesting open problem to analyze these cases explicitly and identify the local correlations (and their reductions).

Example 1. In the first example we return to the case in Section 4.4 and consider

$$V(x) = \tfrac{1}{2}x^2, \qquad \text{and} \qquad W(y) = \tfrac{1}{4}y^4 - \tfrac{2-\tau^2}{2}y^2, \tag{5.3}$$

so we are are on the curve $\alpha = -2+\tau^2$ in the phase diagram in Figure 2. Hence we have $W_{\rm eff}(y) = y^4/4 - y^2$ and hence, in a double scaling limit, the local correlation for the eigenvalues for M_2 are governed by the Painlevé II kernel (2.9). As for the eigenvalues of M_1, from the phase diagram we read off that for $\tau < 1$ the local correlation are given by the sine kernel and for $\tau > 1$ we obtain the Painlevé II kernel. The transition takes place at $\tau = 1$ (and hence $\alpha = -1$) where the kernel has the scaling limit (4.7).

Example 2. In the second example we consider the

$$W(y) = \tfrac{1}{6}y^6 - \tfrac{1}{2^{4/3}}y^4 + \tfrac{1}{2}(-\tfrac{1}{2^{1/3}} + \tau^2)y^2$$

For this potential the equilibrium measure for $W_{\rm eff}$ is given by

$$\frac{\mathrm{d}\mu_{W_{\rm eff}}}{\mathrm{d}x} = \tfrac{4}{\pi}x^4\sqrt{2^{2/3} - x^2},$$

and we have a quartic vanishing at the origin. In this case, the spectral curve (5.3) takes the form

$$2^{-4/3}\xi^2 + \xi^4 + \tau(x - \tau\xi)\left(\tau x + 2^{1/3}\xi - \tau^2\xi + 2^{2/3}\xi^3 - \xi^5\right) = 0,$$

In particular, for $\tau = 2^{-1/3}$ we have

$$x^2 + \xi^6 - x\xi^3(2^{1/3}\xi^2 - 2) = 0,$$

and from here we see that for $x = 0$ the solution $\xi = 0$ has multiplicity six and the origin connects all sheets.

Example 3. In the final example we show that similar phenomena occur when dealing with singular edge points. Consider the potential

$$W(y) = \tfrac{8}{5}y + (\tfrac{1}{5} + \tfrac{\tau^2}{2})y^2 - \tfrac{4}{15}y^3 + \tfrac{1}{20}y^4.$$

In this case, the effective potential $W_{\rm eff}$ gives rise to an equilibrium measure with a singular endpoint

$$\frac{\mathrm{d}\mu_{W_{\rm eff}}}{\mathrm{d}x} = \tfrac{1}{10\pi}(x-2)^2\sqrt{4 - x^2}.$$

See also [16]. For the special case $\tau = \sqrt{5}/5$ the spectral curve takes the form

$$(-32 + 16y - 8y^2 + 4y^3 - y^4) + \sqrt{5}(8 + 4y - 4y^2 + y^3)x - 5x^2 = 0$$

For $x = 4\sqrt{5}/5$ we find four solutions $\xi = 2$ and hence this point connects all sheets.
